Sample Questions from EAS 203 Engineering Mathematics 2 Solved Paper

Question 1: Solve the Differential Equation $\left(\frac{dy}{dx} + y \tan x = \sin^2 x \right)$

Solution:

Step 1: Recognize as a first-order linear ODE.

Step 2: Write in standard form:

$$\left[\frac{dy}{dx} + P(x) y = Q(x) \right]$$

where $\left(P(x) = \tan x \right)$, $\left(Q(x) = \sin^2 x \right)$.

Step 3: Find integrating factor:

$$\left[\mu(x) = e^{\int P(x) dx} = e^{\int \tan x dx} = e^{-\ln |\cos x|} = \frac{1}{\cos x} \right]$$

Step 4: Multiply entire equation by $\left(\mu(x) \right)$:

$$\left[\frac{1}{\cos x} \frac{dy}{dx} + \frac{\tan x}{\cos x} y = \frac{\sin^2 x}{\cos x} \right]$$

which simplifies to:

$$\frac{d}{dx} \left(\frac{y}{\cos x} \right) = \frac{\sin^2 x}{\cos x}$$

Step 5: Integrate both sides:

$$\frac{y}{\cos x} = \int \frac{\sin^2 x}{\cos x} dx + C$$

Using $(\sin^2 x = 1 - \cos^2 x)$:

$$\int \frac{1 - \cos^2 x}{\cos x} dx = \int \frac{1}{\cos x} dx - \int \cos x dx$$

$$= \int \sec x dx - \int \cos x dx$$

$$= \ln |\sec x + \tan x| - \sin x + C$$

Thus:

$$y = \cos x \left(\ln |\sec x + \tan x| - \sin x + C \right)$$

This is the general solution.

These methods have been applied to real-world problems, yielding solutions that are not only theoretically sound but also practically implementable.

Classic Operations Research Problems and Their Resolutions

- The Transportation Problem: Optimizing Logistics and Distribution

Background:

The transportation problem is a classic OR problem that involves determining the most cost-effective way to transport goods from multiple suppliers to multiple consumers, subject to supply and demand constraints.

Historical Context and Solution Approach:

Developed in the 1940s, the transportation problem was initially tackled using the North West Corner method for initial feasible solutions and the Vogel's Approximation Method for better starting points. The optimal solution was typically derived using the Modified Distribution Method (MODI).

Real-World Application:

A manufacturing company needed to distribute products from warehouses to retail outlets. By applying linear programming models, they minimized transportation costs while meeting demand constraints. This approach led to significant cost savings and improved delivery schedules.

Impact and Modern Usage:

Today, advanced algorithms like network simplex and column generation handle large-scale transportation problems efficiently, enabling global supply chain optimization for multinational corporations.

- The Assignment Problem: Efficient Resource Allocation

Background:

The assignment problem involves assigning tasks to agents (e.g., workers to jobs) such that the total cost or time is minimized. It is a special case of the transportation problem with unit supply and demand.

Solution Technique:

The Hungarian Algorithm (also known as the Kuhn-Munkres algorithm), developed in the 1950s, provides a polynomial-time method to find the optimal assignment.

Real-World Example:

Airline crew scheduling is a classic application. Airlines need to assign crews to flights in a way that minimizes total staffing costs while adhering to regulatory and operational constraints.

Results and Benefits:

By implementing the Hungarian Algorithm, airlines can reduce staffing costs, improve crew utilization, and ensure regulatory compliance—all crucial for operational efficiency.

- The Inventory Management Problem: Balancing Cost and Service

Overview:

Inventory management involves determining optimal order quantities and reorder points to minimize total costs—ordering costs, holding costs, and stockout costs.

Operational Research Contribution:

The Economic Order Quantity (EOQ) model is a foundational solution that calculates the ideal order size to minimize total inventory costs. Extensions of EOQ incorporate stochastic demand, lead times, and multiple products.

Case Study:

A retail chain used OR models to optimize stock levels across hundreds of stores. Implementing an EOQ-based system reduced excess inventory and stockouts, leading to increased sales and

decreased warehousing expenses.

Advanced Techniques:

More sophisticated approaches, such as just-in-time (JIT) inventory and dynamic programming, further refine inventory policies to adapt to demand variability.

Advanced Operations Research Applications and Solutions

Outcome:

Network throughput increased significantly, providing better service to customers and reducing operational costs.

- Scheduling Problems: Enhancing Productivity and Service

Scope:

Scheduling involves allocating resources over time to tasks, machines, or personnel, considering constraints such as deadlines, capacities, and precedence.

Example:

In manufacturing, job-shop scheduling problems are solved using heuristic algorithms, genetic algorithms, or simulated annealing to find near-optimal schedules in reasonable timeframes.

Healthcare Applications:

Hospitals use OR techniques to schedule operating rooms, staff shifts, and patient appointments, improving utilization and reducing wait times.

- The Vehicle Routing Problem (VRP): Optimizing Delivery Routes

Challenge:

VRP involves designing the most efficient routes for a fleet of vehicles to serve a set of customers, respecting constraints like vehicle capacity and time windows.

Solution Methods:

Exact algorithms work well for small instances, but for large-scale VRPs, heuristics and metaheuristics such as tabu search or ant colony optimization are employed.

Industry Impact:

Logistics companies like FedEx and DHL utilize advanced VRP solutions to minimize fuel consumption, reduce delivery times, and lower operational costs.

The Evolution of Operations Research Solved Problems

From Exact to Approximate Solutions:

Many initial OR solutions relied on exact algorithms, suitable for small or medium-sized problems. As problem complexity grew, heuristic and metaheuristic methods became essential for providing good solutions within reasonable timeframes.

Integration with Technology:

Advances in computing power, data analytics, and machine learning have expanded OR capabilities. Today, integrated systems can solve large-scale, real-time problems such as dynamic routing during traffic fluctuations or real-time inventory replenishment.

Sustainable and Socially Responsible Operations:

Modern OR also addresses sustainability concerns, optimizing resource use to reduce environmental impact while maintaining service levels.

Sample Solved Problem from DSP Proakis

Problem Statement

Given an LTI system with an impulse response $h[n] = (0.8)^n u[n]$, where $u[n]$ is the unit step function, find the system's output when the input is $x[n] = 2 \cos(\pi n/4)$.

Step-by-Step Solution

1. Recognize the System and Input

The system is linear and time-invariant (LTI), characterized by $h[n]$. The input is a cosine sequence.

2. Express the Input in Complex Exponential Form

Using Euler's formula:

$$x[n] = 2 \cos\left(\frac{\pi n}{4}\right) = \operatorname{Re}\{2 e^{j\pi n/4}\}$$

3. Find the System's Frequency Response $H(e^{j\omega})$

The Z-transform of $h[n]$:

$$H(z) = \sum_{n=0}^{\infty} (0.8)^n z^{-n} = \frac{1}{1 - 0.8 z^{-1}}, \quad |z| > 0.8$$

Evaluate on the unit circle $(z = e^{j\omega})$:

$$H(e^{j\omega}) = \frac{1}{1 - 0.8 e^{-j\omega}}$$

4. Compute $H(e^{j\pi/4})$

Substitute $(\omega = \pi/4)$:

$$H(e^{j\pi/4}) = \frac{1}{1 - 0.8 e^{-j\pi/4}}$$

Calculate numerator and denominator:

$$\frac{1}{1 - 0.8 e^{-j\pi/4}}$$

$$e^{-j\pi/4} = \cos(\pi/4) - j \sin(\pi/4) = \frac{\sqrt{2}}{2} - j \frac{\sqrt{2}}{2}$$

\\

Thus:

\\

$$1 - 0.8 e^{-j\pi/4} = 1 - 0.8 \left(\frac{\sqrt{2}}{2} - j \frac{\sqrt{2}}{2} \right) = 1 - 0.8 \frac{\sqrt{2}}{2} + j 0.8 \frac{\sqrt{2}}{2}$$

\\

Numerical evaluation:

\\

$$0.8 \frac{\sqrt{2}}{2} \approx 0.8 \times 0.7071 \approx 0.5657$$

\\

So:

\\

$$\text{Real part: } 1 - 0.5657 = 0.4343$$

\\

\\

$$\text{Imaginary part: } 0.5657$$

\\

Magnitude:

\\

$$|D| = \sqrt{(0.4343)^2 + (0.5657)^2} \approx \sqrt{0.1886 + 0.3200} \approx \sqrt{0.5086} \approx 0.713$$

\]

Phase:

\[

$$\angle D = \arctan \left(\frac{0.5657}{0.4343} \right) \approx \arctan(1.304) \approx 52.5^\circ$$

\]

Therefore:

\[

$$H(e^{j\pi/4}) = \frac{1}{D} = \frac{1}{|D| e^{j\angle D}} = \frac{1}{0.713 e^{j 52.5^\circ}} = 1.4 e^{-j 52.5^\circ}$$

\]

5. Find the System Output in Frequency Domain

The output's frequency component:

\[

$$Y(\omega) = H(e^{j\omega}) X(\omega)$$

\]

Since:

\[

$$X(\omega) = 2\pi \delta \left(\omega - \frac{\pi}{4} \right) + 2\pi \delta \left(\omega + \frac{\pi}{4} \right)$$

\]

The relevant component:

\[

$$Y(\pi/4) = H(e^{j\pi/4}) \times 2$$

\\

Similarly, the negative frequency component:

\\

$$Y(-\pi/4) = H(e^{-j\pi/4}) \times 2$$

\\

But because the input is real, the output is the sum of these conjugate components.

6. Final Time-Domain Output

The output is:

\\

$$y[n] = \text{Re} \left\{ 2 H(e^{j\pi/4}) e^{j\pi n/4} \right\}$$

\\

Using the calculated $H(e^{j\pi/4})$:

\\

$$|H| = 1.4, \angle H = -52.5^\circ$$

\\

Thus:

\\

$$y[n] = 2 \times 1.4 \times \cos \left(\frac{\pi n}{4} - 52.5^\circ \right) \approx 2.8 \times \cos \left(\frac{\pi n}{4} - 52.5^\circ \right)$$

DSP Proakis Solved Problem: An In-Depth Analytical Review

In the realm of digital signal processing (DSP), the works of John G. Proakis have become a cornerstone for both academic instruction and practical application. Among his many contributions, the solved problems presented in his textbooks serve as essential tools for students and professionals aiming to deepen their understanding of complex DSP concepts. This article offers a comprehensive, analytical review of a typical "DSP Proakis solved problem," exploring its significance, methodology, and implications within the broader context of DSP theory and practice.

Understanding the Significance of DSP Proakis Solved Problems

Proakis' textbooks, especially *Digital Signal Processing: Principles, Algorithms, and Applications*, are revered for their clarity, depth, and rigorous problem sets. These solved problems serve multiple purposes:

- Educational Reinforcement: They help students grasp theoretical concepts through practical application.
- Skill Development: Solving complex problems enhances analytical thinking and problem-solving skills.
- Bridge to Real-World Applications: They simulate scenarios encountered in engineering tasks, fostering readiness for industry challenges.

The solved problems often encompass a broad spectrum—from filtering and Fourier analysis to adaptive systems and multirate processing—reflecting the multifaceted nature of DSP.

Typical Structure of a DSP Proakis Solved Problem

Most solved problems in Proakis' texts follow a structured approach:

- Problem Statement: Clearly defines the DSP challenge, often involving signal analysis, filter design, or system response calculations.
- Given Data: Includes parameters such as signal frequencies, sampling rates, filter coefficients,

etc.

- Required Solution: Specifies what needs to be calculated or demonstrated?e.g., system response, filter characteristics, or spectral analysis.
- Step-by-Step Solution: Breaks down the problem into manageable parts, applying relevant DSP principles, mathematical tools, and algorithms.
- Final Answer and Interpretation: Presents the solution with explanations, highlighting the significance of the results.

This structured methodology not only facilitates learning but also embodies best practices for tackling complex engineering problems.

Analyzing a Typical DSP Proakis Solved Problem: Case Study

To illustrate, let's analyze a representative problem often encountered in Proakis' texts: Designing a Bandpass Filter Using the Fourier Transform.

Problem Overview:

Given a discrete-time signal with a specific spectral content, design a bandpass filter that isolates a frequency band of interest. Calculate the filter's frequency response and verify its effectiveness through simulation.

Step 1: Understanding the Signal and System Requirements

- Signal characteristics: For example, a sampled signal containing components at 500 Hz and 1500 Hz.
- Sampling frequency: 4000 Hz.
- Objective: Filter out the 1500 Hz component, retaining the 500 Hz frequency.

Step 2: Determine Filter Specifications

- Passband: 450 Hz to 550 Hz.
- Stopband: Frequencies outside this range.
- Transition band: Defined based on practical constraints.
- Filter type: Finite Impulse Response (FIR) or Infinite Impulse Response (IIR).

Step 3: Selecting Filter Design Method

Proakis discusses several methods?windowing, Parks-McClellan algorithm, etc. For simplicity,

assume the use of the windowing method:

- Choose an ideal bandpass filter's impulse response.
- Apply a window function (e.g., Hamming, Hann) to obtain a realizable FIR filter.

Step 4: Calculating Filter Coefficients

- Compute ideal impulse response $\{h_d[n]\}$ via inverse Fourier transform.
- Apply window $\{w[n]\}$: $h[n] = h_d[n] \times w[n]$.

Step 5: Analyzing Frequency Response

- Use the Discrete Fourier Transform (DFT) or the Fast Fourier Transform (FFT) to evaluate the filter's frequency response $\{H(e^{j\omega})\}$.
- Verify that the passband is adequately preserved and the stopband attenuation meets specifications.

Step 6: Simulating and Validating

- Generate a test signal containing multiple frequency components.
- Pass it through the designed filter.
- Analyze the output to confirm suppression of unwanted frequencies.

Final Remarks:

This problem encapsulates core DSP concepts: filter design, Fourier analysis, system response, and simulation. It demonstrates how theoretical principles translate into practical filter implementation.

Key Concepts and Techniques Demonstrated in the Solved Problem

The above case study illustrates several essential DSP techniques:

- Fourier Transform and Spectral Analysis: Understanding how signals and filters behave in the frequency domain.
- Filter Design Principles: Translating specifications into filter coefficients through algorithms like windowing.

- Sampling Theorem: Ensuring the sampling rate accommodates the highest frequency component to prevent aliasing.
- Windowing Method: Managing the trade-off between filter length, transition width, and ripple.

These concepts form the backbone of many DSP applications, from audio processing to communications systems.

Interpreting the Results and Practical Implications

The success of the filter design hinges on meeting the specifications?selecting appropriate window functions, filter lengths, and verifying the spectral response. Practical considerations include:

- Computational Efficiency: Longer filters improve selectivity but increase computational load.
- Real-time Constraints: Implementing filters within hardware with limited processing power.
- Robustness: Ensuring stability and minimal distortion over varying operating conditions.

A well-executed DSP problem solution exemplifies the iterative nature of engineering design?balancing ideal performance with real-world constraints.

Broader Perspectives: Learning from Proakis' Approach

Proakis' problems emphasize a thorough understanding of DSP fundamentals paired with analytical rigor. This approach fosters:

- Critical Thinking: Encouraging students to question assumptions and explore alternative solutions.
- Mathematical Rigor: Reinforcing the importance of precise calculations and reasoning.
- Application-Oriented Learning: Connecting theoretical insights with industry-relevant problems.

Moreover, the solved problems serve as templates for tackling complex, multi-step challenges in advanced DSP applications.
